

Notes for High-Dimensional Probability: Random Vectors in High Dimensions

Isak Falk & Dimitri Meunier

April 12, 2021

1 Preliminaries

Proposition 1. *Let X be a real-valued random variable and $Y = \sqrt{|X|}$. Then X is sub-exponential if and only if Y is sub-Gaussian, and in such case $\|X\|_{\psi_1} = \|Y\|_{\psi_2}^2$*

Proposition 2. *Let X be a real-valued sub-exponential variable, then the centered random variable $X - \mathbb{E}X$ is sub-exponential and*

$$\|X - \mathbb{E}X\|_{\psi_1} \leq (1 + \frac{2}{\ln 2})\|X\|_{\psi_2}. \quad (1)$$

Proof. The proof is analogous to the sub-Gaussian case but with different constant since the definition of the norm is different,

$$\|X - \mathbb{E}X\|_{\psi_1} \leq \|X\|_{\psi_1} + \|\mathbb{E}X\|_{\psi_1}, \quad (2)$$

and

$$\|\mathbb{E}X\|_{\psi_1} = \frac{|\mathbb{E}X|}{\ln 2} \leq \frac{\mathbb{E}|X|}{\ln 2} = \frac{\|X\|_1}{\ln 2} \leq \frac{2}{\ln 2}\|X\|_{\psi_1}, \quad (3)$$

where we have used the definition of sub-exponential norm for constant functions, Jensen and bound of L^p norm of X by sub-exponential norm. We thus have that $\|X - \mathbb{E}X\|_{\psi_1} \leq (1 + \frac{2}{\ln 2})\|X\|_{\psi_1}$ which is what we wanted to show.

□

Theorem 3 (Bernstein's inequality). *Let $(X_i)_{i=1}^n$ be a sequence of independent real-valued zero-mean random variables such that $\|X_i\|_{\psi_1} < \infty$. Then, for every $t > 0$*

$$\mathbb{P}(|\frac{1}{n} \sum_{i=1}^n X_i| > t) \leq 2 \exp(-cn \min(\frac{t^2}{K^2}, \frac{t}{K})), \quad (4)$$

where $K = \max_i \|X_i\|_{\psi_1}$ and $c > 0$ is some absolute constant.

2 Concentration of the Norm

Theorem 4 (Concentration of the L_2 norm). *Let $X = (X_1, \dots, X_n) \in \mathbb{R}^n$ be a random vector with independent sub-gaussian coordinates X_i that satisfy $\mathbb{E}X_i^2 = 1$. Then*

$$\left\| \|X\|_2 - \sqrt{n} \right\|_{\psi_2} \leq CK^2, \quad (5)$$

where $K = \max_i \|X_i\|_{\psi_2}$ and C is an absolute constant.

Proof. We first note that $K \geq 1$. By Jensen's Inequality we have that $\mathbb{E} \exp(\frac{X_i^2}{t^2}) \geq \exp(\frac{\mathbb{E}X_i^2}{t^2}) = \exp(t^{-2})$ and using $t = 1$ we see that $\mathbb{E} \exp(X_i^2) \geq e > 2$ so $\|X_i\|_{\psi_2} \geq 1$ for all $i \in \{1, \dots, n\}$. Since $K = \max_i \|X_i\|_{\psi_2} \geq 1$ we are done.

Now consider the quantity $\frac{1}{n} \|X\|_2^2 - 1$ which we can write as

$$\frac{1}{n} \|X\|_2^2 - 1 = \frac{1}{n} \sum_{i=1}^n (X_i^2 - 1) = \frac{1}{n} \sum_{i=1}^n Y_i, \quad (6)$$

where $Y_i = X_i^2 - 1$. Since $\mathbb{E}X_i^2 = 1$ for any i , $(Y_i)_{i=1}^n$ is a vector of zero-centred random variables. Since $\|X_i\|_{\psi_2} < \infty$ we can show that $\|Y_i\|_{\psi_1} < \infty$ since

$$\|X_i^2 - 1\|_{\psi_1} \leq C \|X_i^2\|_{\psi_1} \quad (7)$$

$$= C \|X_i\|_{\psi_2}^2 \quad (8)$$

$$\leq CK^2, \quad (9)$$

using centring property of sub-exponentials proposition 2 (noting that $C > 1$), proposition 1 and definition of K . Since $(Y_i)_{i=1}^n$ are independent, zero-mean and by the above calculation sub-exponential, we can apply Bernstein's Inequality Thm. 3 which for any $u \geq 0$ means that

$$\mathbb{P}(|\frac{1}{n} \sum_{i=1}^n Y_i| > u) \leq 2 \exp(-cn \min(\frac{u^2}{C^2 K^4}, \frac{u}{CK^2})) \quad (10)$$

for some $c > 0$. Since $C, K > 1$ we have that $C^2 > C$ and $K^4 > K^2$, so we can write

$$\exp(-cn \min(\frac{u^2}{C^2 K^4}, \frac{u}{CK^2})) \leq \exp(-\frac{cn}{C^4 K^4} \min(u^2, u)). \quad (11)$$

So far we have proved a concentration bound on $\|X\|_2^2$. We will finish the proof by relating $\|X\|_2$ to $\|X\|_2^2$. Note the following; for any $z, \delta \geq 0$

$$|z - 1| \geq \delta \Rightarrow |z^2 - 1| \geq \max(\delta, \delta^2). \quad (12)$$

We show it by first noting that $|z^2 - 1| = |z - 1||z + 1| \geq |z + 1|\delta$, and see that if $\delta \in [0, 1)$ then $|z + 1| \geq \delta$ and if $\delta \geq 1$ then since $|z + 1| \geq 1$ we have that $|z^2 + 1| \geq \delta$. We can write this compactly as (12).

Now, consider any $\delta \geq 0$ and the expression $\left| \frac{1}{\sqrt{n}} \|X\|_2 - 1 \right| \geq \delta$. Using (12) with $z = \frac{1}{\sqrt{n}} \|X\|_2$ we see that

$$\left| \frac{1}{\sqrt{n}} \|X\|_2 - 1 \right| \geq \delta \Rightarrow \left| \frac{1}{n} \|X\|_2^2 - 1 \right| \geq \max(\delta, \delta^2). \quad (13)$$

In terms of events, this means that

$$\mathbb{P}(\left| \frac{1}{\sqrt{n}} \|X\|_2 - 1 \right| \geq \delta) \leq \mathbb{P}(\left| \frac{1}{n} \|X\|_2^2 - 1 \right| \geq \max(\delta, \delta^2)) \leq 2 \exp(-\frac{cn}{C^4 K^4} \delta^2), \quad (14)$$

where in the final inequality we have used (11) together with

$$\delta^2 = \min(\max(\delta, \delta^2), \max(\delta, \delta^2)^2). \quad (15)$$

Letting $t = \delta\sqrt{n}$ we obtain the bound

$$\mathbb{P}(\left| \|X\|_2 - \sqrt{n} \right| \geq t) \leq 2 \exp(-\frac{ct^2}{C^4 K^4}), \quad (16)$$

for any $t \geq 0$ and this is equal to the conclusion of the theorem. \square

Remark 1. The above bound tells us that with high probability, X takes values very close to the sphere of radius \sqrt{n} . In particular, for a fixed probability X stays within a constant distance from that sphere independently of the dimension n . This is due to the fact that $\|X\|_2^2$ has mean n and standard deviation $O(\sqrt{n})$ since

$$\mathbb{V}(\|X\|_2^2) = \sum_{i=1} \mathbb{V}(X_i^2) = n\mathbb{V}(X_1^2), \quad (17)$$

due to independence of the coordinates of X , and so $\sqrt{\mathbb{V}(\|X\|_2^2)} = \sqrt{n} \cdot \text{std}(X_1^2)$. $\sqrt{n} \pm O(\sqrt{n}) = \sqrt{n} \pm O(1)$ since by Taylor expansion around \sqrt{n} on the interval $[n - c\sqrt{n}, n + c\sqrt{n}]$ where c need to be chosen so that $n - c\sqrt{n} \geq 0$ we see that

$$\sqrt{n \pm c\sqrt{n}} = \sqrt{n} + R_1(c\sqrt{n}) \quad (18)$$

where $R_1(x) = [\text{Need to fill in}]$.

3 Covariance, second moments, whitening and isotropy

Definition 1. The covariance matrix of a random vector $X \in \mathbb{R}^n$ is

$$\text{Cov}(X) = \mathbb{E}(X - \mathbb{E}X)(X - \mathbb{E}X)^\top = \mathbb{E}XX^\top - \mathbb{E}X(\mathbb{E}X)^\top. \quad (19)$$

Definition 2. The second moment matrix of a random vector $X \in \mathbb{R}^n$ is

$$\Sigma = \Sigma(X) = \mathbb{E}XX^\top. \quad (20)$$

Note that if $\mathbb{E}X = 0$, then $\text{Cov}(X) = \Sigma(X)$. So we can mostly consider the second moment matrix without loss of generality in place of the covariance as long as we center our variable X . Both of the matrices are symmetric and positive semi-definite.

Definition 3. A random vector $X \in \mathbb{R}^n$ is called isotropic if

$$\Sigma(X) = \mathbb{E}XX^\top = I. \quad (21)$$

For a random variable $X \in \mathbb{R}^n$ with covariance matrix Σ and mean μ we can always put it into a isotropic form by whitening $Z = \Sigma^{-1/2}(X - \mu)$. Similarly, the transformation using a psd matrix Σ , $X = \mu + \Sigma^{1/2}Z$ of a mean-zero isotropic random vector $Z \in \mathbb{R}^n$ leads to a random vector with mean μ and covariance Σ . This observation means that in many cases we may focus on random isotropic mean-zero random vectors without loss of generality.

Lemma 5. A random vector $X \in \mathbb{R}^n$ is isotropic if and only if

$$\mathbb{E}\langle X, u \rangle = \|u\|^2 \quad (22)$$

for all $u \in \mathbb{R}^n$. Equivalently we could have used

$$\mathbb{E}\langle X, u \rangle = 1 \quad (23)$$

for all $u \in S^{n-1}$, the n -dimensional unit sphere.

Proof. Two symmetric matrices A, B are equal if and only if $x^\top Ax = x^\top B$ for any $x \in \mathbb{R}^n$. Thus X is isotropic if and only if

$$u^\top \mathbb{E}XX^\top u = \mathbb{E}\langle X, u \rangle = u^\top Iu = \|u\|_2^2 \quad (24)$$

for all $u \in \mathbb{R}^n$ which is what we wanted to show. \square

Lemma 6. Let X be an isotropic random vector in \mathbb{R}^n . The

$$\mathbb{E}\|X\|_2^2 = n. \quad (25)$$

Moreover, if X, Y are two independent isotropic random vectors in \mathbb{R}^n , then

$$\mathbb{E}\langle X, Y \rangle^2 = n \quad (26)$$

Proof. First we have

$$\mathbb{E}\|X\|_2^2 = \mathbb{E}X^\top X \quad (27)$$

$$= \mathbb{E}\text{Tr}(XX^\top) \quad (28)$$

$$= \text{Tr}(\mathbb{E}XX^\top) \quad (29)$$

$$= \text{Tr}(I) \quad (30)$$

$$= n. \quad (31)$$

For the second part we use the so called *law of total expectation* to write

$$\mathbb{E}\langle X, Y \rangle = \mathbb{E}_X \mathbb{E}_Y(\langle x, Y \rangle | X = x) = \mathbb{E}_X \|X\|_2^2 = n \quad (32)$$

by the Lemma 5 and reusing the first part of the proof. \square

Corollary 7. *Let X, Y be independent mean-zero isotropic random vectors in \mathbb{R}^n , then*

$$\mathbb{E}\|X - Y\|_2^2 = 2n \quad (33)$$

Proof.

$$\mathbb{E}\|X - Y\|_2^2 = \mathbb{E}\|X\|_2^2 + \mathbb{E}\|Y\|_2^2 - 2\mathbb{E}\langle X, Y \rangle \quad (34)$$

$$= 2n - 0 \quad (35)$$

$$= 2n \quad (36)$$

\square

4 Examples of high-dimensional distributions

Let $X \sim \text{Unif}(\sqrt{n}S^{n-1})$ mean that the law of X is the uniform measure on the zero-centered sphere of radius \sqrt{n} in n dimensions.

Theorem 8 (Isotropy of uniform random variable on $\sqrt{n}S^{n-1}$).
